→ Small Demo on RAG QA with Product Features of Apple iOS 17

Overview

Large Language Models (LLMs) have improved quantitatively and qualitatively. They can learn new abilities without being directly trained on them. However, there are constraints with LLMs - they are unaware of events after training and it is almost impossible to trace the sources to their responses. It is preferred for LLM based systems to cite their sources and be grounded in facts.

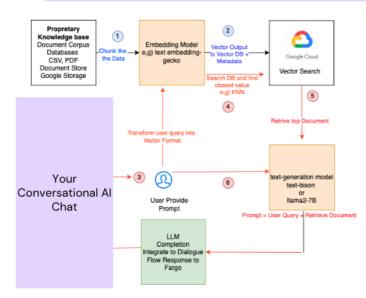

To solve for the constraints, one of the approaches is to augment the prompt sent to LLM with relevant data retrieved from an external knowledge base through Information Retrieval (IR) mechanism. This approach is called Retrieval Augmented Generation (RAG), also known as Generative QA in the context of the QA task. There are two main components in RAG based architecture: (1) Retriever and (2) Generator.

- Retriever: The knowledge base is integrated with an IR mechanism, also known as a Retriever, to retrieve relevant snippets from documents based on the user's query. The knowledge base can be your own document corpus, databases, or APIs. The Retriever can be implemented using term-based search (e.g. keyword, TF-IDF). Another approach is to use vector search based on dense embeddings, which captures semantically rich information in the text, leading to much more efficient information retrieval. The relevant snippets retrieved from the IR mechanism are passed as "context" to the next stage, Generator.
- **Generator:** The context relevant snippets from the knowledge base are passed to an LLM to generate a well formed response grounded by the source documents.

This approach extracts relevant info from knowledge base to respond to queries, avoiding LLM memory limits and hallucinations. An added advantage is you can keep knowledge base up-to-date with new documents, ensuring grounded, accurate, relevant responses.

▼ High Level Flow

Following is the high level flow of implementation:

laaC: Use Terraform- Provision Resource Create a Storage, VPC, Private Access Point, Model Registry, Vector search, Use Google Function with event trigger once object placed in Google storage.

- Upload the PDF object to Google Storage. Trigger a Google function to split the data into individual pages and store them in Google Storage. Execute another function to invoke the Embedding Model, converting the text into vectors.
- 2) Store the vector output in the Vector Search database.
- 3 and 4) Users submit queries via the Chat window. Transform chat requests into vectors. Search the Vector DB using K-Nearest Neighbors (KNN) or Artificial Neural Networks (ANN) to identify the closest matching values.
- Retrieve the top-ranked documents. Combine the retrieved documents with user input. Pass this data to the LLM (Language Model) to generate an output.
- 6) Parse the output from the LLM Model, Orchestrate the entire workflow using LangChain. Send the resulting response back to the Chat window

Following are the sequence of tasks when ingesting knowledge base sources into the vector store:

- Read the documents (PDF files in this notebook)
- · Chunk the documents to include relevant parts of the document as context to the prompt
- · Generate embeddings for each chunked document
- · Add embedding to the vector store

Following is the data flow at runtime when user prompts the model:

- · User enters a prompt or asks a question as a prompt
- Generated embedding for the user prompt to capture semantics
- Search the vector store to retrieve the nearest embeddings (relevant documents) closer to the prompt
- · Fetch the actual text for the retrieved embeddings to add as context to the user's prompt
- · Add the retrieved documents as context to the user's prompt
- · Send the updated prompt to the LLM
- · Return a summarized response to the user with references to the sources from the knowledge base

Objective

This notebooks demonstrates implementing a QA system based on retrieval augmented generation pattern that responds to questions based on a private collection of documents and adds references to the relevant documents. The datasets used as a private document corpus is a sample of Google published research papers.

You will learn how to:

- Use LangChain RetrievalQA chain with built-in integration for Vertex AI PaLM API for <u>Text</u>, <u>Embeddings API</u> and <u>Vertex AI Vector</u>
 <u>Search</u>
- Extract text from PDF files stored on Cloud Storage bucket
- 🛮 Generate embeddings using Vertex AI Embedding API to generate embeddings to capture semantics
- Wertex AI Vector Search as a managed vector store on cloud to store the generated embeddings
- Query Matching Engine index and return relevant results
- Vertex Al PaLM API for Text as LLM to synthesize results and respond to the user query

NOTE: The notebook uses custom Matching Engine wrapper with LangChain to support streaming index updates and deploying index on public endpoint.

Getting Started

Install Vertex AI SDK, other packages and their dependencies

Install the following packages required to execute this notebook.

```
1 # Install Vertex AI LLM SDK
2 ! pip install --user --upgrade google-cloud-aiplatform==1.31.0 langchain==0.0.201
```

^{4 #} Dependencies required by Unstructured PDF loader

```
5 ! sudo apt -y -qq install tesseract-ocr libtesseract-dev
 6 ! sudo apt-get -y -qq install poppler-utils
7 ! pip install --user unstructured==0.7.5 pdf2image==1.16.3 pytesseract==0.3.10 pdfminer.six==20221105
9 # For Matching Engine integration dependencies (default embeddings)
10 ! pip install --user tensorflow_hub==0.13.0 tensorflow_text==2.12.1
```

```

Restart current runtime

To use the newly installed packages in this Jupyter runtime, you must restart the runtime. You can do this by running the cell below, which will restart the current kernel.

Consider adding this directory to PATH or, if you prefer to suppress this warning, use --no-warn-script-location.

```
Downloading tensorflow hub-0.13.0-py2.py3-none-any.whl (100 kB)
1 # Automatically restart kernel after installs so that your environment can access the new packages
2 import IPython
4 app = IPython.Application.instance()
5 app.kernel.do_shutdown(True)
   {'status': 'ok', 'restart': True}
```

Before proceeding, please wait for the kernel to finish restarting

Authenticating your notebook environment

If you are using Colab, you will need to authenticate yourself first. The next cell will check if you are currently using Colab, and will start the authentication process.

If you are using Vertex AI Workbench, you will not require additional authentication.

For more information, you can check out the setup instructions here.

▼ Initialize LangChain Models

You initialize LangChain Models with the pre-trained text, chat and embeddings generation model called text-bison@001, chat-bison@001 and textembedding-gecko@001 respectively.

```
1 # Text model instance integrated with langChain
 2 llm = VertexAI(
      model_name="text-bison@001",
      max output tokens=1024,
 5
      temperature=0.2,
      top p=0.8,
 7
      top_k=40,
 8
      verbose=True,
9)
11 # Embeddings API integrated with langChain
12 EMBEDDING QPM = 100
13 EMBEDDING_NUM_BATCH = 5
14 embeddings = CustomVertexAIEmbeddings(
     requests_per_minute=EMBEDDING_QPM,
15
16
      num_instances_per_batch=EMBEDDING_NUM_BATCH,
17)
```

▼ STEP 1: Create Matching Engine Index and Endpoint for Retrieval

<u>Embeddings</u> are a way of representing data as n-dimensional vector, in a space where the locations of those points in space are semantically meaningful. These embeddings can be then used to find similar data points. You can get text embeddings using <u>Vertex AI Embeddings API</u>. These embeddings are managed using a vector database.

<u>Vertex Al Matching Engine</u> is a Google Cloud managed vector database, which stores data as high-dimensional vectors (embeddings) and can find the most similar vectors from over a billion vectors. Matching Engine's Approximate Nearest Neigbors (ANN) service can serve similarity-matching queries at high queries per second (QPS). Unlike vector stores that run locally, Matching Engine is optimized for scale (multi-million and billion vectors) and it's an enterprise ready engine.

As part of the environment setup, create an index on Vertex Al Matching Engine and deploy the index to an Endpoint. Index Endpoint can be <u>public</u> or <u>private</u>. This notebook uses a **Public endpoint**.

Refer to the Matching Engine documentation for details.

A NOTE: Please note creating an Index on Matching Engine and deploying the Index to an Index Endpoint can take up to 1 hour.

- Configure parameters to create Matching Engine index
 - ME REGION: Region where Matching Engine Index and Index Endpoint are deployed
 - ME INDEX NAME: Matching Engine index display name
 - ME EMBEDDING DIR: Cloud Storage path to allow inserting, updating or deleting the contents of the Index
 - ME_DIMENSIONS: The number of dimensions of the input vectors. Vertex AI Embedding API generates 768 dimensional vector embeddings.

Make a Google Cloud Storage bucket for your Matching Engine index

· Create a dummy embeddings file to initialize when creating the index

▼ Create Index

You can create index on Vertex AI - Vector search for batch updates or streaming updates.

This notebook creates Vector search Index:

- With streaming updates
- With default configuration e.g. small shard size

You can <u>update the index configuration</u> in the Vector search utilities script.

While the index is being created and deployed, you can read more about Matching Engine's ANN service which uses a new type of vector quantization developed by Google Research: <u>Accelerating Large-Scale Inference with Anisotropic Vector Quantization</u>.

For more information about how this works, see Announcing ScaNN: Efficient Vector Similarity Search.

```
1 mengine = MatchingEngineUtils(PROJECT_ID, ME_REGION, ME_INDEX_NAME)
```

```
1 index = mengine.create index(
```

```

▼ Deploy Index to Endpoint

Vector Search

Deploy index to Index Endpoint on Matching Engine. This notebook deploys the index to a public endpoint. The deployment operation creates a public endpoint that will be used for querying the index for approximate nearest neighbors.

For deploying index to a Private Endpoint, refer to the <u>documentation</u> to set up pre-requisites.

```
1 index endpoint = mengine.deploy index()
2 if index_endpoint:
     print(f"Index endpoint resource name: {index endpoint.name}")
5
         f"Index endpoint public domain name: {index endpoint.public endpoint domain name}"
6
     print("Deployed indexes on the index endpoint:")
8
     for d in index_endpoint.deployed_indexes:
         print(f"
                     {d.id}")
   ......Index endpoint resource name: projects/880171706777/locations/us-central1/indexEndpoints/86491542882
   Index endpoint public domain name:
   Deployed indexes on the index endpoint:
```

STEP 2: Add Document Embeddings to Matching Engine - Vector Store

This step ingests and parse PDF documents, split them, generate embeddings and add the embeddings to the vector store. The document corpus used as dataset is a sample of Google published research papers across different domains - large models, traffic simulation, productivity etc.

Ingest PDF files

The document corpus is hosted on Cloud Storage bucket (at gs://github-repo/documents/google-research-pdfs/) and LangChain provides a convenient document loader GCSDirectoryLoader to load documents from a Cloud Storage bucket. The loader uses Unstructured package to load files of many types including pdfs, images, html and more.

Make a Google Cloud Storage bucket in your GCP project to copy the document files into.

```
1 GCS_BUCKET_DOCS = f"{PROJECT_ID}-documents"
2 ! set -x && gsutil mb -p $PROJECT ID -l us-central1 gs://$GCS BUCKET DOCS
   + gsutil mb -p conversationai-401012 -l us-centrall gs://conversationai-401012-documents
   Creating gs://conversationai-401012-documents/...
```

Copy document files to your bucket

```
1 folder_prefix = "documents/ios-feature-pdfs/"
2 ! wget https://www.apple.com/ios/ios-17/pdf/iOS All New Features.pdf
3 ! gsutil cp -r iOS_All_New_Features.pdf gs://$GCS_BUCKET_DOCS/$folder_prefix
   --2023-10-07 11:40:49-- https://www.apple.com/ios/ios-17/pdf/iOS_All_New_Features.pdf

```

Load documents and add document metadata such as file name, to be retrieved later when citing the references.

```
1 # Ingest PDF files
 3 print(f"Processing documents from {GCS_BUCKET_DOCS}")
 4 loader = GCSDirectoryLoader(
      project_name=PROJECT_ID, bucket=GCS_BUCKET_DOCS, prefix=folder_prefix
 6)
 7 documents = loader.load()
 9 \# Add document name and source to the metadata
10 for document in documents:
11
      doc md = document.metadata
      document_name = doc_md["source"].split("/")[-1]
      # derive doc source from Document loader
13
14
      doc_source_prefix = "/".join(GCS_BUCKET_DOCS.split("/")[:3])
     doc source suffix = "/".join(doc_md["source"].split("/")[4:-1])
15
      source = f"{doc_source_prefix}/{doc_source_suffix}"
16
17
      document.metadata = {"source": source, "document_name": document_name}
18
19 print(f"# of documents loaded (pre-chunking) = {len(documents)}")
    Processing documents from conversationai-401012-documents
    [nltk_data] Downloading package punkt to /root/nltk_data...
    [nltk data] Unzipping tokenizers/punkt.zip.
    [nltk_data] Downloading package averaged_perceptron_tagger to
    [nltk_data]
                  /root/nltk_data...
    [nltk_data] Unzipping taggers/averaged_perceptron_tagger.zip.
    # of documents loaded (pre-chunking) = 1
```

Verify document metadata

```
1 documents[0].metadata
   {'source': 'conversationai-401012-documents/ios-feature-pdfs',
     document_name': 'iOS_All_New_Features.pdf'}
```

▼ Chunk documents

Split the documents to smaller chunks. When splitting the document, ensure a few chunks can fit within the context length of LLM.

```
1 # split the documents into chunks
 2 text_splitter = RecursiveCharacterTextSplitter(
      chunk_size=1000,
      chunk_overlap=50,
      separators=["\n\n", "\n", ".", "!", "?", ",", " ", ""],
 6)
 7 doc splits = text splitter.split documents(documents)
 9 # Add chunk number to metadata
10 for idx, split in enumerate(doc_splits):
11
      split.metadata["chunk"] = idx
12
13 print(f"# of documents = {len(doc_splits)}")
```

```
# of documents = 62
1 doc_splits[0].metadata
   {'source': 'conversationai-401012-documents/ios-feature-pdfs',
     document_name': 'iOS_All_New_Features.pdf',
    'chunk': 0}
```

Configure Matching Engine as Vector Store

Get Matching Engine Index id and Endpoint id

```
1 ME_INDEX_ID, ME_INDEX_ENDPOINT_ID = mengine.get_index_and_endpoint()
2 print(f"ME INDEX ID={ME INDEX ID}")
3 print(f"ME_INDEX_ENDPOINT_ID={ME_INDEX_ENDPOINT_ID}")
  ME_INDEX_ID=projects/880171706777/locations/us-central1/indexes/3340536227509043200
```

Initialize Matching Engine vector store with text embeddings model

```
1 \; \# \; \text{initialize vector store}
2 me = MatchingEngine.from_components(
     project id=PROJECT ID,
     region=ME_REGION,
     gcs_bucket_name=f"gs://{ME_EMBEDDING_DIR}".split("/")[2],
5
     embedding=embeddings,
     index id=ME INDEX ID,
     endpoint_id=ME_INDEX_ENDPOINT_ID,
9)
```

Add documents as embeddings in Matching Engine as index

The document chunks are transformed as embeddings (vectors) using Vertex AI Embeddings API and added to the index with streaming index update. With Streaming Updates, you can update and query your index within a few seconds.

The original document text is stored on Cloud Storage bucket had referenced by id.

Prepare text and metadata to be added to the vectors

```
1 # Store docs as embeddings in Matching Engine index
2 \ \# It may take a while since API is rate limited
3 texts = [doc.page_content for doc in doc_splits]
4 metadatas = [
5
      Γ
          {"namespace": "source", "allow_list": [doc.metadata["source"]]},
6
7
          {"namespace": "document_name", "allow_list": [doc.metadata["document_name"]]},
          {"namespace": "chunk", "allow_list": [str(doc.metadata["chunk"])]},
8
9
10
      for doc in doc splits
11 1
```

Add embeddings to the vector store

NOTE: Depending on the volume and size of documents, this step may take time.

```
1 doc ids = me.add texts(texts=texts, metadatas=metadatas)
   Waiting
```

Validate semantic search with Matching Engine is working

```
1 # Test whether search from vector store is working
2 me.similarity_search("What is Improved Autocorrect accuracy.", k=2)
```

```
Waiting
```

STEP 3: Retrieval based Question/Answering Chain

LangChain provides easy ways to chain multiple tasks that can do QA over a set of documents, called QA chains. The notebook works with RetrievalQA chain which is based on load_qa_chain under the hood.

In the retrieval augmented generation chain, the Matching Engine uses semantic search to retrieve relevant documents based on the user's question. The resulting documents are then added as additional context to the prompt sent to the LLM, along with the user's question, to generate a response. Thus the response generated by LLM is grounded to your documents in the corpus.

This way, a user would only need to provide their question as a prompt and the retrieval chain would be able to seek the answers using Matching Engine directly, and return a proper text response answering the question.

Configure Question/Answering Chain with Vector Store using Text

Define Matching Engine Vector Store as retriever that takes in a query and returns a list of relevant documents. The retriever implementation supports configuring number of documents to fetch and filtering by search distance as a threshold value parameter.

```
1 # Create chain to answer questions
2 NUMBER_OF_RESULTS = 10
3 SEARCH DISTANCE THRESHOLD = 0.6
5 # Expose index to the retriever
6 retriever = me.as retriever(
     search_type="similarity",
8
      search kwargs={
9
          "k": NUMBER_OF_RESULTS,
          "search distance": SEARCH DISTANCE THRESHOLD,
10
11
      },
12)
```

Customize the default retrieval prompt template

```
1 template = """SYSTEM: You are an intelligent assistant helping the users with their questions on new Product.
 3 Question: {question}
 5 Strictly Use ONLY the following pieces of context to answer the question at the end. Think step-by-step and then answer
 7 Do not try to make up an answer:
 8 - If the answer to the question cannot be determined from the context alone, say "I cannot determine the answer to that
  - If the context is empty, just say "I do not know the answer to that."
10
11 ========
12 {context}
13 =======
14
15 Question: {question}
16 Helpful Answer:"
```

Configure RetrievalQA chain

```
1 # Uses LLM to synthesize results from the search index.
 2 # Use Vertex PaLM Text API for LLM
 3 qa = RetrievalQA.from_chain_type(
      llm=llm,
 5
      chain_type="stuff",
 6
      retriever=retriever,
 7
      return_source_documents=True,
     verbose=True,
 9
     chain_type_kwargs={
10
          "prompt": PromptTemplate(
11
              template=template,
              input_variables=["context", "question"],
12
13
          ),
14
      },
15)
```

Enable verbose logging for debugging and troubleshooting the chains which includes the complete prompt to the LLM

```
1 # Enable for troubleshooting
2 qa.combine_documents_chain.verbose = True
3 qa.combine_documents_chain.llm_chain.verbose = True
4 qa.combine_documents_chain.llm_chain.llm.verbose = True
```

Utility function to format the result

```
1 def formatter(result):
     print(f"Query: {result['query']}")
      print("." * 80)
 3
      if "source_documents" in result.keys():
 5
          for idx, ref in enumerate(result["source_documents"]):
              print("-" * 80)
 6
              print(f"REFERENCE #{idx}")
 7
 8
              print("-" * 80)
9
              if "score" in ref.metadata:
10
                  print(f"Matching Score: {ref.metadata['score']}")
             if "source" in ref.metadata:
11
12
                  print(f"Document Source: {ref.metadata['source']}")
13
              if "document name" in ref.metadata:
14
                  print(f"Document Name: {ref.metadata['document_name']}")
15
              print("." * 80)
              print(f"Content: \n{wrap(ref.page_content)}")
16
17
     print("." * 80)
18
      print(f"Response: {wrap(result['result'])}")
19
      print("." * 80)
2.0
21
22 def wrap(s):
      return "\n".join(textwrap.wrap(s, width=120, break_long_words=False))
23
24
25
26 def ask(query, qa=qa, k=NUMBER OF RESULTS, search distance=SEARCH DISTANCE THRESHOLD):
27
      qa.retriever.search_kwargs["search_distance"] = search_distance
28
      qa.retriever.search_kwargs["k"] = k
29
      result = qa({"query": query})
      return formatter(result)
```

▼ Run QA chain on sample questions

Following are sample questions you could try. Wehn you run the query, RetrievalQA chain takes the user question, call the retriever to fetch top k semantically similar texts from the Matching Engine Index (vector store) and passes to the LLM as part of the prompt. The final prompt sent to the LLM looks of this format:

where:

- system: Instructions for LLM on how to respond to the question based on the context
- context: Semantically similar text (a.k.a snippets) retreived from the vector store
- question: question posed by the user

The response returned from the LLM includes both the response and references that lead to the response. This way the response from LLM is always grounded to the sources. Here we have formatted the response as:

1 ask("Tell me about Explicit language handling.")

completed perore in as little as a single tap. Improvement to Siri voices for voiceOver. Siri voices sound even bett at high rates of speech feedback in VoiceOver. iOS 17 New Features | September 2023 9 Fitness+23 Sections. Organi reminders within a list by creating headers to group related reminders. Open in Pages. Create a Pages document from your note with a quick selection from the Share menu.

New widget options for Home Screen and Lock Scree make running shortcuts more convenient. Multilayered photo effect for photo shuffle. Subjects can be dynamically displayed in front of the time to make the subject of the photo pop. Text Display Podcasts Vertical text support. Chinese and Japanese text can be displayed vertically in supported apps and components like Contact Posters, Photos Memories, and Calendar widgets. Improved playback controls. Easily access your queue, playback speed, and sleep time Astronomy wallpapers. See the earth, moon, and other planets in the solar system with a set of dynamic astronomy-them Lock Screens that update with live conditions, like your live location on Earth, or based on the time of day on Mars.

Response: An embedded photo picker for apps lets you pick photos to share within the app's experience, without sharin library. When an app does ask to access your entire library, you'll see details of how many and which photos will be shared before you make a decision. If you grant access, you'll receive reminders from time to time.

Let's ask a question which is outside of the domain in the corpus. You should see something like - "I cannot determine the answer to that". This is because the output is conditioned in the prompts to not to respond when the question is out of the context.

Following is the instructions in prompt template that is configured in the retrieval QA chain above:

Strictly Use ONLY the following pieces of context to answer the question at the end. Think step-by-step and then answer. Do not try to make up an answer: - If the answer to the question cannot be determined from the context alone, say "I cannot determine the answer to that." - If the context is empty, just say "I do not know the answer to that." 1 ask("Where is 2023 Cricket world cup happening") > Entering new chain...
